## Supplementary Text 1. Details on the assessment of lifestyle, metabolic parameters, and genetic risk score.

Information on lifestyle factors (smoking, physical activity, healthy diet), as well as metabolic parameters (body-mass-index [BMI], type 2 diabetes mellitus [T2DM], hypertension, high and low density lipoprotein cholesterol [HDL-C, LDL-C]) were gathered via a standardized face-toface interview and medical exams by trained medical staff as well as laboratory measurements. Participants were classified as current smokers (including regular smokers, currently smoking $\geq 1$ cigarette per day, and occasional smokers, currently smoking $<1$ cigarette per day), exsmokers, and never smokers. Physical activity was assessed as regular activity during leisure time in summer and/or winter weekly for $\geq 1$ hour (active) or less (not active). ${ }^{2}$ A score for healthy diet was computed based on a 24-item standardized questionnaire ${ }^{3}$ and dichotomized at the median of 15.00 (healthy diet: score $\geq 15.00$, no healthy diet: score $<15.00$ ). BMI (kg $\mathrm{m}-2$ ) was computed based on measured weight in kg (in light clothing, to nearest 0.1 kg ) and height in m (to nearest 0.5 cm ) as weight divided by squared body height. ${ }^{4}$ T2DM was assessed as self-reported type 2 diabetes or reported anti-diabetic therapy intake. ${ }^{1}$ Hypertension was assessed as actually measured systolic blood pressure of $\geq 140 \mathrm{mmHg}$, diastolic blood pressure of $\geq 90 \mathrm{mmHg}$ or corresponding medication taken, given that the participants were aware of having hypertension. ${ }^{1}$ HDL-C and LDL-C was measured as described previously. ${ }^{5}$

For genetic data, KORA and AugUR study participants were genotyped via the Affymetrix Axiom (Thermo Fisher Scientific, Santa Clara, California, USA) or the Illumina Infinium Global Screening Array (Illumina, San Diego, California, USA) and genetic information was imputed (1000 Genomes Reference panel, phase 3, version 5). ${ }^{6}$ We derived information for 50 of 52 variants identified from case-control studies for late AMD $^{7}$ (49 variants directly and a proxy for rs142450006, rs1888235, with $r^{2}=0.96$ in IAMDGC data ${ }^{7}$ ). The variants rs121913059 and rs141853578 were rare (minor allele frequency in IAMDGC <= 1\%) and unavailable in AugUR and KORA. Most of these 50 genetic variants were also documented
risk factors for early AMD. ${ }^{8}$ We computed a genetic risk score (GRS) by adding the dosages of AMD risk alleles, weighed by the respective variant's effect size (log odds ratio from fully conditioned regression model ${ }^{7}$ ) and divided by the theoretical maximum of the weighted sum (i.e., the sum of two times the effect size for each variant). This resulted in a percentage of the (maximum) GRS for each study participant, ranging theoretically from $0 \%$ to $100 \%$, observed from 32.0\% to $54.0 \%$ (mean $\pm$ standard deviation: $43.3 \pm 3.9,43.1 \pm 3.9,43.7 \pm 3.7$ for KORA-Fit, KORA-FF4 and AugUR, respectively).

## Supplementary Text 2. Details on the acquisition, processing, and grading of color fundus images.

In order to achieve comparable image quality across all three studies and all follow-up visits, the same camera type, settings and protocol were used in all studies/visits conducted in 20132019. KORA-S4 was conducted in 1999-2001; here, color fundus images of the central retina were acquired using the $45^{\circ}$ non-mydriatic TRC-NW5S fundus camera (Topcon, Willich, Germany). As described previously ${ }^{1}$, at least one non-stereoscopic color fundus photograph of the central retina of each eye, including full macular region and optic disc, was acquired. Images were available as.jpg-files with a resolution of $768 \times 576$ pixels. In AugUR1-BL, AugUR1-FU1, KORA-FF4 and KORA-Fit, conducted in 2013-2019, the automatized DRS camera (Digital Retinography System; CenterVue, Padova, Italy) with identical settings was applied as described before ${ }^{9,10}$ : at least two color fundus images of each eye were acquired capturing the central or the central nasal field of the retina within a $45^{\circ}$ view, including the full macular region and optic disc. Color fundus images were exported as .jpg-files with a resolution of $2,592 \times 1,944$ pixels from the DRS camera.

As it is known that the quality of fundus photography depends on pupil size and that pupil size decreases with age ${ }^{11}$, mild pharmacological mydriasis was administered for the majority of the individuals aged 70+ as described previously. ${ }^{9}$ Additionally, KORA-Fit participants with non-gradable images for at least one eye were re-invited to the Department of Ophthalmology, University Hospital Augsburg, where a total of 50 individuals were then re-
examined in mild mydriasis using the Zeiss FF450 plus color fundus camera (Carl Zeiss AG, Oberkochen, Germany; Supplementary Table 1A).

The following steps of processing and grading were exactly the same across the three studies and for baseline and follow-up. (1) All images were imported into the K-DRS software, a self-developed application for image analysis: images are displayed with a standardized front end on a 27 inch color-calibrated monitor, information on quality and grading can be entered, and results are linked with image number, participant identifier (IDGenerator ${ }^{12}$ ). (2) All images were assessed for gradability and for AMD by the same grader (C.B.). (3) Images were defined as gradable for AMD, if they fulfilled the following quality criteria allowing for the assessment of AMD: sufficient brightness and color contrast as well as full macular region captured. Images were excluded from AMD grading, if they revealed obscuring lesions (e.g. cataract) or lesions considered to be the result of a competing retinal disease hampering AMD grading (such as advanced diabetic retinopathy, high myopia, trauma, congenital diseases, or photocoagulation unrelated to choroidal neovascularization). (4) Details of assessing AMD features for each eye have been described previously ${ }^{1,9}$ : The presence of drusen and pigment abnormalities (hyperpigmentation or depigmentation) on color fundus images was assessed. Only lesions within 2 standard disc diameters (approx. $3000 \mu \mathrm{~m}$ ) of the centre of the macula/fovea were considered. To determine drusen size category (small, intermediate, large), the smallest drusen diameter was compared to the width of a major branch retinal vein crossing the optic disc margin, considered to be approximately one-twelfth disc diameter (i.e. $125 \mu \mathrm{~m}$, assuming the average disc diameter to be $1500 \mu \mathrm{~m})$. Drusen were defined as small drusen when their diameter were $\leq$ half the diameter of the vein (i.e. $\leq 63 \mu \mathrm{~m}$ ), as large drusen for $\geq$ full diameter of the vein (i.e. $\geq 125 \mu \mathrm{~m}$ ), and as intermediate drusen if anything in between (> $63 \mu \mathrm{~m}$ and $<$ $125 \mu \mathrm{~m})$. For borderline findings, the K-DRS image analysis software semi-automatically facilitated the measurement of drusen diameter, when the two distant points of the smallest drusen diameter were manually clicked by the grader. To assess total drusen area, the K-DRS software allowed for digitally placing a circle with $650 \mu \mathrm{~m}$ in diameter on the image, which helped the grader to categorize total drusen area as $<$ or $\geq$ the circle area. GA was defined as
an area of RPE atrophy $\geq$ a circle with $350 \mu \mathrm{~m}$ in diameter, central or paracentral localization, and the presence of at least two of the following features: sharply demarcated boarder, lack of RPE, visible choroidal vessels, and circular shape. Pure GA was defined if central or paracentral GA, but no MNV was present; pure MNV was defined if MNV, but no GA was present; mixed GA/MNV was defined if both, GA and MNV were detected. This information on the assessed AMD features was then transferred into AMD stages for each eye at baseline and follow-up by a SAS-algorithm, according to two well-established classification systems: (i) the Three Continent AMD Consortium Severity Scale (3CACSS) ${ }^{13}$, which separates mild early from moderate or severe early AMD stages depending on drusen size, drusen area, or the presence of pigmentary abnormalities and (ii) the Clinical Classification (CC) ${ }^{14}$, which distinguishes between early and intermediate AMD depending on the presence of large drusen and/or pigmentary abnormalities (further details as described previously ${ }^{9}$ ). These two classification systems differ in how they define "early" or "intermediate" AMD, but the definition of late AMD as presence of GA and/or MNV is fairly similar. (5) AMD status of a participant was derived as the AMD status of the eye with the more severe AMD stage ("worse eye") when both eyes were gradable, and as the grade of the one available eye otherwise. Participants with gradable images for at least one eye at baseline and follow-up were included in the present analysis.

Of note, among the analyzed KORA subjects, eight participants had available AMD status in Fit as well as FF4 (same AMD status) and we chose to assign these individuals to KORA-Fit (younger age at baseline, longer time to follow-up).

## Supplementary Text 3. Details on double grading and baseline versus follow-up comparisons.

All images, from baseline and follow-up in each of the three studies (KORA-S4, KORA-FF4, KORA-Fit, AugUR1-BL, AugUR1-FU1), were graded for AMD features by the same experienced and trained ophthalmological consultant (C.B.) as described before ${ }^{1,9}$; questionable findings were discussed with a second trained grader (ophthalmological
consultant, T.B.). Double grading was performed by these two graders for AugUR, KORA-S4 and FF4; inter-rater reliability was high in AugUR (quadratic weighted kappa=0.97) ${ }^{9,15}$, as well as in KORA (quadratic weighted kappa=0.80 and 0.91 for KORA-S4 and KORA-FF4, respectively).

Initially, images were graded sequentially and independently for baseline and followup, i.e. the grader was masked for the follow-up or baseline grading, respectively. Images that showed regression in AMD status in follow-up compared to baseline were re-graded comparatively in a side-by-side view to evaluate potential misclassification. ${ }^{16}$ Regression from early to no AMD was found in 32 participants (e.g. for 3CACSS: $n=8, n=3, n=21$ in KORA-Fit, KORA-FF4 and AugUR, respectively), regression from late to early/no AMD in one participant (KORA-Fit). After the update via the side-by-side comparison, regression from early to no AMD remained in six participants ( $n=0, n=1$ and $n=5$ participants of KORA-Fit, KORA-FF4, and AugUR, respectively). These results were used for further analysis.

## Supplementary Text 4. Details on statistical analyses.

We computed cumulative incidence and progression estimates, per study and also by refined five- to ten-year age-groups within study, as the number of "events" divided by the number of "persons at risk", as defined above.

The classification of "early AMD" differs between 3CACSS and CC and, consequently, also the classification of "no AMD" (i.e. absence of early and late AMD). The "late AMD" classification is basically the same. We thus computed cumulative incidence and progression for 3CACSS-based AMD and for CC-based AMD. We compared the two classifications of "early AMD" by computing the Positive Predictive Value (PPV) for late AMD as the ratio of the total number of incident late AMD cases among individuals with the respective no/early AMD category divided by the total number of persons within that particular category. We also computed the sensitivity and specificity of no/early AMD baseline categories (consecutively combined based on increasing severity) to predict late AMD development and the respective area under the receiver operating curve (AUROC).

We estimated the association of reported risk factors with incident early AMD, incident late AMD (definition-2), or progression, for each study separately. For this, we applied multiple logistic regression including all risk factors as covariates with early AMD (yes/no) or late AMD (yes/no) at follow-up as outcome and restricting the respective analyses to no AMD at baseline (incident early), no/early AMD at baseline (incident late definition-2), or early AMD at baseline (progression), respectively. Odds ratios (OR) were derived and tested for statistically significant difference from unity. Association with progression was only computed in AugUR, since the number of participants with progression from early to late AMD in the other two studies was not sufficient for stable association estimation. All models were adjusted for the individual's time in follow-up, which was close to 18-year, 14-years, or 3-years in the three studies.

For comparison between our studies and to published studies, we estimated incidence and progression rates per 1,000 person-years by study and refined age-groups. For each agegroup, the rate is derived as the fraction of the number of events divided by the number of person-years at risk, multiplied by 1,000. Each individual contributed the number of years at risk to one or several age-groups corresponding to the person's age at baseline and follow-up, which covered the age range of 35 years up to nearly 100 years (minimum baseline age and maximum age at follow-up).

## Supplementary Table 2. Baseline characteristics of analyzed subjects compared to

participants not in follow-up. Shown are baseline characteristics for subjects with available AMD status at baseline and follow-up (i.e. gradable color fundus images for at least one eye at baseline and follow-up; =analyzed subjects) and for eligible subjects with available AMD status at baseline but not at follow-up (=no follow-up). Also indicated is a significant P -value for difference via logistic regression adjusting for age and/or sex (where applicable).

## Supplementary Figure 1. Age distribution of analyzed KORA and AugUR study

participants. Depicted are numbers of individuals, mean follow-up time [ $25^{\text {th }}$ and $75^{\text {th }}$ percentile], age at baseline and follow-up for each of the three studies: the younger adults (baseline age 35-55 years; KORA-FIT), the older adults (54-75 years; KORA-FF4) and the oldaged (70-95 years; AugUR).

Supplementary Table 3. Cumulative estimates for incident early AMD, incident late AMD, and progression by study and refined age-groups based on the Clinical Classification (CC). Shown are 18-year, 14-year, and 3-year cumulative estimates and 95\%-confidence intervals (CI) for incidence and progression for the three studies (KORA-Fit, KORA FF4, AugUR, respectively), overall and by refined age-groups. For AMD classification, CC ${ }^{14}$ was applied here (analogous estimates for $3 C A C S S{ }^{13}$ in Table 1).

${ }^{\text {a }}$ ) age at baseline
${ }^{\text {b }}$ ) number of events / number of persons at risk
${ }^{\text {c }}$ ) considering individuals with no AMD at baseline (definition-1);
${ }^{\text {d) }}$ considering individuals with no or early AMD at baseline (definition-2);

Supplementary Figure 2. Comparing two classification systems for prediction of late AMD development. An individual's no or early AMD classification at baseline can be considered a screening test to predict development of late AMD. We evaluated 3CACSS ${ }^{13}$ and $C^{17}$ as 3-category and 5-category version. For each of the three studies (18-, 14-, or 3-year follow-up, respectively), we derived (A) positive predictive value (PPV) for incident late AMD by baseline categories for no/early AMD (i.e. cumulative number of incident late AMD cases per no/early AMD category at baseline divided by total number of persons in the category). We also provide (B) sensitivity and 1-specificity per baseline category to discriminate correctly who developed late AMD during follow-up (sensitivity) or wrongly those who did not (1-specificity) and area-under-the-curve of the receiver-operating characteristics (AUROC) as measure for discriminatory ability.

#### Abstract

Supplementary Table 4. Risk factor association with incident early AMD, incident late AMD, and progression. We estimated absolute risk (i.e. probability, Prob, of an individual to be in the reference group) and relative risk (Odds Ratios, OR) including 95\%-confidence intervals $(\mathrm{CI})$ and P -values via logistic regression models. Shown are estimates of $(\mathbf{A})$ incident early, (B) incident late AMD (definition-2), and (C) progression. Covariates were age, sex, follow-up (FU) time, smoking, HDL-C (model I), adding the 50-variant genetic risk score (GRS) (model II) and, for (B), also early AMD at baseline (BL; 3CACSS, without and with GRS, model III and IV, respectively). Model II results for incident early AMD and progression and Model IV results for incident late AMD are depicted in Figure 1.

## Supplementary Table 5. Incidence and progression rates as well as derived 1-year and

3-year risk. Shown are estimates (Est), standard error (SE) and 95\% confidence intervals (CI) of rates (per 1000 person-years; PY) and derived 1-year and 3-year risk (\%) for (A) incident early $A M D,(B)$ incident late AMD among individuals with no AMD at baseline (definition-1), (C) incident late AMD among individuals with no or early AMD at baseline (definition-2), and (D) progression from early to late AMD (also depicted in Figure 2). For AMD classification, 3CACSS was applied. These main analyses assumed that the event occurred at half of the follow-up time.

## Supplementary Table 6. Sensitivity analyses with alternative onset of events for

 incidence and progression rates and derived 1-year and 3-year risk. Shown are estimates and $95 \%$ confidence intervals (CI) of rates (per 1000 person-years) and derived 1-year and 3year risk (\%) for (A) incident early AMD, (B) incident late AMD among individuals with no AMD at baseline (definition-1), (C) incident late AMD among individuals with no or early AMD at baseline (definition-2), and (D) progression from early to late AMD. For AMD classification, 3CACSS was applied. These sensitivity analyses assumed event at $2 / 3$ rd of follow-up time.(A) Incident early AMD (among individuals with no AMD at baseline)
