In vitro efficacy of topical ophthalmic antiseptics against SARS-CoV-2

Shedding of SARS-CoV-2 in tears of patients with COVID-19 has been reported, which could serve as a source of infection for healthy individuals, including healthcare providers. The current standard antiseptic solutions used in ophthalmology in the setting of inoffice procedures and operating rooms include povidone-iodine (PVI) 5% and chlorhexidine gluconate (CHX) 0.1% or 0.05%, which are at concentrations that are lower than those used in other surgical specialties. Although laboratory and clinical studies to date have aimed to evaluate the virucidal benefits of routine PVI use for ophthalmic surgeries, currently there are no established guidelines regarding the optimal contact time and efficacy of varying dilutions as well as comparisons with other formulations such as CHX. Rigorous evaluation of the efficacy of virucidal agents for disinfecting ocular surface of potentially infected patients with SARS-CoV-2 is critical in mitigating the risk of transmission.

In the current study, we evaluated the virucidal efficacy and contact times for commonly used ophthalmic concentrations of PVI and CHX against SARS-CoV-2 using Vero E6 cells as indicator cell lines for residual viable virus based on previously established methodologies (online supplemental appendix). PVI (5% weight per volume, w/v) and CHX (0.05% and 0.1% w/v) were tested at full strength. Fifty microlitres of ophthalmic formulation were added to 10 µL of a SARS-CoV-2 suspension (viral transport media) and incubated at room temperature for varying contact times. A total of three experiments were conducted for PVI and CHX, each including three biological replicates per time point. Individual viral titres for each biological replicate were calculated based on five replicate wells per dilution. Viable residual SARS-CoV-2 was quantified by the Reed-Muench median tissue culture infectious dose (TCID₅₀) procedure in Vero E6 cells. Additional efficacy testing using 1:4 and 1:16 dilutions in phosphate buffered saline were performed in order to mimic clinical settings where dilution of the formulations occurs as a result of mixing with patients’ ocular secretions. Cytotoxicity of residual PVI and CHX was predetermined at all test concentrations using uninfected Vero E6 cells.

No SARS-CoV-2 was detected with PVI at full strength and 1:4 dilution after 60s, 5 min and 10 min of contact time (figure 1). The 1:16 PVI dilution substantially decreased viral titres after 60s of contact time (4.45, SD 0.4 vs 0.12, SD 0.24 log₁₀ TCID₅₀/mL, 95% CI of difference 3.53 to 5.13, p<0.001). No virus was recovered from the inoculated suspensions after 5 and 10 min of contact time with the 1:16 PVI dilution. Full strength CHX 0.1% (3.99, SD 0.1 vs 3.74, SD 0.10 log₁₀ TCID₅₀/mL, 95% CI 0.04 to 0.46, p=0.03) and CHX 0.05% (4.3, SD 0.5 vs 4.53, SD 0.44 log₁₀ TCID₅₀/mL, 95% CI −1.30 to 0.84, p=0.58) concentrations did not result in SARS-CoV-2 inactivation even after 30 min of contact time.

The findings from this in vitro study demonstrate that PVI at commonly used ophthalmic concentration of 5% has greater virucidal activity than CHX against SARS-CoV-2 in inoculated suspensions, with CHX proving to be ineffective at full concentration of 0.1% even after 30 min of contact time. The virucidal benefits of routine PVI in reducing patients’ ocular surface viral load may be effective at 1:16 of the initial concentration with only 60s of contact time. It is important to note that CHX 0.1% w/v is at the upper limit of the concentration commonly used in ophthalmic procedure settings. These findings are in keeping with previous findings which have shown the efficacy of PVI in managing upper respiratory
tract infections and suggested the use of PVI on the sinonasal and oral mucosa against the transmission of SARS-CoV-2. Overall, this study has important implications for clinicians when selecting an ophthalmic solution for routine procedures that reduce transmissibility of SARS-CoV-2 via ocular secretions among patients and healthcare providers. The adoption of guidelines for ophthalmic surgeries such as lacrimal surgeries using PVI may be useful in decreasing viral burden in the setting of the COVID-19 pandemic and other viral infections.

**Figure 1**  Virucidal efficacy of ophthalmic formulations of povidone-iodine (PVI) and chlorhexidine gluconate (CHX) against SARS-CoV-2. (A and B) Mean (±SD) titre of the positive control (inoculum, 0 min contact time) and the postneutralisation samples (60 s, 5 min and 10 min contact time) with PVI 5% at 1:4 and 1:16 dilutions, respectively. (C and D) Mean (±SD) titre of the positive control (inoculum, 0 min contact time) and the postneutralisation samples (60 s, 5 min, 10 min and 30 min of contact time) with CHX 0.1% and 0.05%, respectively. The horizontal dashed lines indicate the limit of detection (LOD) of the assay. Note that the LOD is higher for CHX (1.8 log_{10} TCID_{50}/mL) than PVI (0.8 log_{10} TCID_{50}/mL) due to its cytotoxicity on Vero E6 cells. TCID_{50}, tissue culture infectious dose; w/v, weight per volume.
